# Standardizing-Marine-Biological-Data

Brett Johnson

2020-05-22

2

# Contents

Biological data structures, definitions, measurements, and linkages are necessarily as diverse as the systems they represent. This presents a real challenge when integrating data across biological research domains such as ecology, oceanography, fisheries, and climate sciences.

# Chapter 1

# Introduction

This is about stacking the right standards for your desired ineroperability with other data types. For example, interopating fish biology measurements with climate level variables. There are a few links neccessary to make this possible. This will permit ecosystem based models.

## 1.1 Data Structures

The OBIS-ENV Darwin Core Archive Data Structure.

OBIS manual

## 1.2 Ontologies

An ontology is a classification system for establishing a hierarchically related set of concepts. Concepts are often terms from controlled vocabularies.

From Marine Metadata:

"Ontologies can include all of the following, but are not required to include them, depending on which perspective from above you adhere to:

Classes (general things, types of things) Instances (individual things) Relationships among things Properties of things Functions, processes, constraints, and rules relating to things"

Unified Modeling Language?

## 1.3   Controlled Vocabularies

There are a number of controlled vocabularies that are used to describe parameters commonly used in a research domain. This allows for greater interoperability of data sets.

- Climate and Format (CF) Standard Names are applied to sensors for application with OPeNDAP web service.

- Device categories using the SeaDataNet device categories in NERC 2.0

- Device make/model using the SeaVoX Device Catalogue in NERC 2.0,

- Platform categories using SeaVoX Platform Categories in NERC 2.0

- Platform instances using the ICES Platform Codes in NERC 2.0

- Unit of measure

- GCMD Keywords

- Geographic Domain/Features of Interest

There are numberous ways to investigate which controlled vocabulary to use and this can be fairly overwhelming. For a simplified overview see here.

Note: To describe a measurement or fact of a biological specimen that conforms to Darwin Core standards, it's neccessary to use the 'Biological entity described elsewhere' method rather than taxon specific.

### 1.3.5 Geosciences

'UDUNITS' are more common in geosciences

UDUNITS

### 1.3.6 Eco/EnvO

Environment Ontology including genomics.

### 1.3.7 Wild Cards

P01 Biological Entity Parameter Code Builder

## 1.4 Technologies

### 1.4.1 ERDDAP

ERDDAP provides 'easier access to scientific data' by providing a consistent interface that aggregates many disparate data sources. It does this by providing translation services between many common file types for gridded arrarys ('net CDF' files) and tabular data (spreadsheets). Data access is also made easier because it unifies different types of data servers and access protocols. Here is a basic erddap installation that walks you through how to load a data set.

## 1.5 Notes on Integrating OBIS, Darwin Core as it relates to OOS's

## 1.6 Metadata

OBIS uses the GBIF EML profile (version 1.1). In case data providers use ISO19115/ISO19139, there is a mapping available here: http://rs.gbif.org/schema/eml-gbif-profile/1.1/eml2iso19139.xsl This will be important for integrating OBIS datasets to OOS metadata profiles.

## 1.7 Data QC

There are a number of tools available to check the quality of data or check your data format against the expected standard.

### 1.7.1 Compliance Checking

LifeWatch Belgium provides a number of tools to check your data against. Specifically you can test OBIS data format and see a map of your sample locations to check if they are on land. See http://www.lifewatch.be/data-services/

### 1.7.2   Semantic Web and Darwin Core

Lessons learned from adapting the Darwin Core vocabulary standard for use in RDF

### 1.7.3   Resource Description Framework

Darwin Core Resource Description Framework Guide

# Chapter 2

# Salmon Ocean Data

## 2.1 Intro

One of the goals of the Hakai Institute and the Canadian Integrated Ocean
Observing System (CIOOS) is to facilitate Open Science and FAIR (findable,
accessible, interoperable, reusable) ecological and oceanographic data. In a
concerted effort to adopt or establish how best to do that, several Hakai and
CIOOS staff attended an International Ocean Observing System (IOOS) Code
Sprint in Ann Arbour, Michigan between October 7–11, 2019, to discuss how
to implement FAIR data principles for biological data collected in the marine
environment.

The Darwin Core is a highly structured data format that standardizes data ta-
ble relations, vocabularies, and defines field names. The Darwin Core defines
three table types: `event`, `occurrence`, and `measurementOrFact`. This intu-
itively captures the way most ecologists conduct their research. Typically, a
survey (event) is conducted and measurements, counts, or observations (collec-
tively measurementOrFacts) are made regarding a specific habitat or species
(occurrence).

In the following script I demonstrate how I go about converting a subset of the
data collected from the Hakai Institute Juvenile Salmon Program and discuss
challenges, solutions, pros and cons, and when and what's worthwhile to convert
to Darwin Core.

The conversion of a dataset to Darwin Core is much easier if your data are
already tidy (normalized) in which you represent your data in separate tables
that reflect the hierarchical and related nature of your observations. If your data
are not already in a consistent and structured format, the conversion would likely
be very arduos and not intuitive.

## 2.2   event

The first step is to consider what you will define as an event in your data set.
I defined the capture of fish using a purse seine net as the `event`. Therefore,
each row in the `event` table is one deployment of a seine net and is assigned a
unique `eventID`.

My process for conversion was to make a new table called `event` and map the
standard Darwin Core column names to pre-existing columns that serve the
same purpose in my original `seine_data` table and populate the other required
fields.

```r
event <- tibble(eventID = survey_seines$seine_id,
                eventDate = date(survey_seines$survey_date),
                decimalLatitude = survey_seines$lat,
                decimalLongitude = survey_seines$long,
                geodeticDatum = "EPSG:4326 WGS84",
                minimumDepthInMeters = 0,
                maximumDepthInMeters = 9, # seine depth is 9 m
                samplingProtocol = "http://dx.doi.org/10.21966/1.566666" # This is the
                )

write_csv(event, here::here("datasets", "hakai_salmon_data", "event.csv"))
```

## 2.3   occurrence

Next you'll want to determine what constitutes an occurrence for your data
set. Because each event caputers fish, I consider each fish to be an occurrence.
Therefore, the unit of observation (each row) in the occurrence table is a fish. To
link each occurence to an event you need to include the `eventID` column for every
occurrence so that you know what seine (event) each fish (occurrence) came from.
You must also provide a globally unique identifier for each occurrence. I already
have a locally unique identifier for each fish in the original `fish_data` table
called `ufn`. To make it globally unique I pre-pend the organization and research
program metadata to the `ufn` column.

```r
#TODO: Include bycatch data as well

## make table long first
seines_total_long <- survey_seines %>%
  select(seine_id, so_total, pi_total, cu_total, co_total, he_total, ck_total) %>%
  pivot_longer(-seine_id, names_to = "scientificName", values_to = "n")

seines_total_long$scientificName <- recode(seines_total_long$scientificName, so_total =

seines_taken_long <- survey_seines %>%
```

```r
  select(seine_id, so_taken, pi_taken, cu_taken, co_taken, he_taken, ck_taken) %>%
  pivot_longer(-seine_id, names_to = "scientificName", values_to = "n_taken")

seines_taken_long$scientificName <- recode(seines_taken_long$scientificName, so_taken = "Oncorhy

## remove records that have already been assigned an ID
seines_long <-  full_join(seines_total_long, seines_taken_long, by = c("seine_id", "scientificNam
  drop_na() %>%
  mutate(n_not_taken = n - n_taken) %>% #so_total includes the number taken so I subtract n_taken
  select(-n_taken, -n) %>%
  filter(n_not_taken > 0)

all_fish_caught <-
  seines_long[rep(seq.int(1, nrow(seines_long)), seines_long$n_not_taken), 1:3] %>%
  select(-n_not_taken) %>%
  mutate(prefix = "hakai-jsp-",
         suffix = 1:nrow(.),
         occurrenceID = paste0(prefix, suffix)
  ) %>%
  select(-prefix, -suffix)

#

# Change species names to full Scientific names
latin <- fct_recode(fish_data$species, "Oncorhynchus nerka" = "SO", "Oncorhynchus gorbuscha" = "P
  as.character()

fish_retained_data <- fish_data %>%
  mutate(scientificName = latin) %>%
  select(-species) %>%
  mutate(prefix = "hakai-jsp-",
         occurrenceID = paste0(prefix, ufn)) %>%
  select(-semsp_id, -prefix, -ufn, -fork_length_field, -fork_length, -weight, -weight_field)

occurrence <- bind_rows(all_fish_caught, fish_retained_data) %>%
  mutate(basisOfRecord = "HumanObservation",
         occurenceStatus = "present") %>%
  rename(eventID = seine_id)
```

For each occuerence of the six different fish species that I caught I need to match the species name that I provide with the official `scientificName` that is part of the World Register of Marine Species database http://www.marinespecies.org/

```r
# I went directly to the WoRMS webite (http://www.marinespecies.org/) to download the full taxono

species_matched <- readxl::read_excel(here::here("datasets", "hakai_salmon_data", "raw_data", "sp
```

```r
occurrence <- left_join(occurrence, species_matched, by = c("scientificName" = "Scient
  select(occurrenceID, basisOfRecord, scientificName, eventID, occurrenceStatus = occu

#write_csv(occurrence, here::here("datasets", "hakai_salmon_data", "occurrence.csv"))
```

## 2.4  measurementOrFact

To convert all your measurements or facts from your normal format to Darwin
Core you essentially need to put all your measurements into one column called
measurementType and a corresponding column called measurementValue. This
standardizes the column names are in the `measurementOrFact` table. There are
a number of predefined `measurementType`s listed on the NERC database that
should be used where possible. I found it difficult to navigate this page to find
the correct `measurementType`.

Here I convert length, and weight measurements that relate to an event and an
occurrence and call those `measurementTypes` as `length` and `weight`.

```r
fish_data$weight <- coalesce(fish_data$weight, fish_data$weight_field)
fish_data$fork_length <- coalesce(fish_data$fork_length, fish_data$fork_length_field)

fish_length <- fish_data %>%
  mutate(occurrenceID = paste0("hakai-jsp-", ufn)) %>%
  select(occurrenceID, eventID = seine_id, fork_length, weight) %>%
  mutate(measurementType = "fork length", measurementValue = fork_length) %>%
  select(eventID, occurrenceID, measurementType, measurementValue) %>%
  mutate(measurementUnit = "millimeters",
         measurementUnitID = "http://vocab.nerc.ac.uk/collection/P06/current/UXMM/")

fish_weight <- fish_data %>%
  mutate(occurrenceID = paste0("hakai-jsp-", ufn)) %>%
  select(occurrenceID, eventID = seine_id, fork_length, weight) %>%
  mutate(measurementType = "mass", measurementValue = weight) %>%
  select(eventID, occurrenceID, measurementType, measurementValue) %>%
  mutate(measurementUnit = "grams",
         measurementUnitID = "http://vocab.nerc.ac.uk/collection/P06/current/UGRM/")

measurementOrFact <- bind_rows(fish_length, fish_weight) %>%
  drop_na(measurementValue)

rm(fish_length, fish_weight)

#write_csv(measurementOrFact, here::here("datasets", "hakai_salmon_data", "measurement
```

# Chapter 3

# Methods

We describe our methods in this chapter.

# Chapter 4

# Applications

Some *significant* applications are demonstrated in this chapter.

## 4.1  Example one

## 4.2  Example two

# Chapter 5

# Final Words

We have finished a nice book.
